**ERLICHIA CANIS**

Ehrlichia Canis <1:80 <1:80

----- INTERPRETIVE COMMENT -----

IgG LESS THAN 1:80 (NEGATIVE)

There is no serologic evidence of exposure to Ehrlichia canis. However, a negative titer does not rule out exposure to other species. Also, some acutely infected dogs and cats are clinically ill prior to seroconversion. If clinical signs of ehrlichiosis are present, institute treatment and repeat serologic testing in 3 weeks to assess for increasing titers.

IgG GREATER THAN OR EQUAL TO 1:80

A positive titer supports exposure to E. canis or cross-reactive Ehrlichia spp (E. ewingii or E. chaffeensis). If clinical signs of ehrlichiosis are present, institute treatment and repeat serologic testing in 3 weeks to assess for increasing titers.

Persistent titers beyond 9 months of initial diagnosis may indicate a carrier state or re-exposure.

**LYME TITER (IgG)**

Lyme IgG Antibody **Borderline(1)**

APPROXIMATE TITER EQUIVALENT <1:64=Negative 1=1:64-1:128 2=1:256 3=1:512 4=>OR = 1:1024

*Started doxycycline 55-1*

----- INTERPRETIVE COMMENT -----

IgM(<1:16) and IgG(<1:64) = Negative OR IgG <1:64 (only) = Negative

There is no serologic evidence of exposure to Borrelia burgdorferi, the causal agent of Lyme disease.

IgM (<1:16) Negative, IgG > or = 1:64 OR IgG (only) = >1:64

These results are most consistent with vaccination and/or natural exposure to Borrelia burgdorferi. A Lyme western blot can differentiate between vaccination and natural exposure. If clinical signs of Lyme disease are present consider instituting treatment.

IgM > or = 1:16, IgG(<1:64) Negative or IgG > or = 1:64

Accession No. MECT02748674	Doctor HEFLIN	Owner GINA	Patient Name CITY
Test Requested	Results	Reference Range	Units

These results are most consistent with vaccination and/or natural exposure to *Borrelia burgdorferi*. A Lyme western blot can differentiate between vaccination and natural exposure. If clinical signs of Lyme disease are present consider instituting treatment.

ROCKY MOUNTAIN SPOTTED FEVER ( <i>RICKETTSIA RICKETTSII</i> ) RMSP (IFA)	Neg	<1:64	Titer
---	-----	-------	-------

*hiding below 1:64*

----- INTERPRETIVE COMMENT -----

Single titers greater than or equal to 1:1024 are consistent with active infection.

Dogs tested during the active phase of disease may have a negative or low positive serology. Documentation of a 4 fold rise in titer 2 to 3 weeks following the initial blood sampling supports recent infection.

Most dogs exposed to *R. rickettsii* are subclinically infected, therefore, positive serology indicates exposure, not necessarily disease. Also, dogs exposed to nonpathogenic spotted fever rickettsii can develop antibodies that cross react with the assay.
